  typedef pair<int, int> pii;
  vector<vector<int>> adj;
  vector<bool> visited;
  vector<int>> vahs;
  void dfs(int u) {
    visited[u] = true;
    for (int to : adj[u]) {
```

3 Dynamic Programming

3.1 Divide and Conquer Optimization

Reduces the complexity from $O(n^2k)$ to $O(nk \log n)$ of PD's in the following ways (and other variants):

$$dp[n][k] = \max_{0 \leq i < n} \bigl(dp[i][k-1] + C[i+1][n] \bigr), \ base \ case : \ dp[0][j], dp[i][0] \qquad (1 + 1)[n] = \max_{0 \leq i < n} \bigl(dp[i][k] - 1 \bigr) + C[i+1][n] \bigr)$$

- C[i][j] = the cost only depends on i and j.
- opt[n][k] = i is the optimal value that maximizes dp[n][k].

It is necessary that opt is increasing along each column: $opt[j][k] \leq opt[j+1][k]$.

3.2 Divide and Conquer Optimization Implementation

```
#include <bits/stdc++.h>
using namespace std;
int C(int i, int j);
const int MAXN = 100010;
const int MAXK = 110;
const int INF = 0x3f3f3f3f3f;
int dp[MAXN][MAXK];
void calculateDP(int 1, int r, int k, int opt_1, int opt_r) {
  if (1 > r)
    return;
  int mid = (1 + r) >> 1;
  int ans = -INF, opt;
  for (int i = opt_l; i <= min(opt_r, mid - 1); i++) {</pre>
    if (ans < dp[i][k - 1] + C(i + 1, mid)){
      opt = i;
      ans = dp[i][k-1] + C(i+1, mid);
  dp[mid][k] = ans;
```

```
calculateDP(1, mid - 1, k, opt_l, opt);
calculateDP(mid + 1, r, k, opt, opt_r);
}
int solve(int n, int k) {
  for (int i = 0; i <= n; i++)
    dp[i][0] = -INF;
  for (int j = 0; j <= k; j++)
    dp[0][j] = -INF;
  dp[0][0] = 0;
  for (int j = 1; j <= k; j++)
    calculateDP(1, n, j, 0, n - 1);
  return dp[n][k];
}</pre>
```

  vk.resize(mx, 0);
 prevC3(p - 1, p);
  int ans = 1;
  for (int i = 0; i < mx; i++)
    ans = (ans * 1LL * C3(vn[i], vk[i], p)) % p;
  return ans;
```

4.3 Chinese Remainder Theorem

```
#include <bits/stdc++.h>
#include "extended euclidean.h"
using namespace std;
typedef long long 11;
namespace CRT {
  inline ll normalize(ll x, ll mod) {
    x \% = mod;
    if (x < 0)
      x += mod;
    return x;
  11 solve(vector<11> a, vector<11> m) {
    int n = a.size();
    for (int i = 0; i < n; i++)</pre>
      normalize(a[i], m[i]);
    ll ans = a[0];
    11 \ lcm1 = m[0];
    for (int i = 1; i < n; i++) {</pre>
      11 x, y;
      ll q = extGcd(lcm1, m[i], x, y);
      if ((a[i] - ans) % q != 0)
        return -1;
      ans = normalize(ans + ((((a[i] - ans) / q) * x) % (m[i] / q)) *
          lcm1, (lcm1 / q) * m[i];
      lcm1 = (lcm1 / q) * m[i]; //lcm(lcm1, m[i]);
    return ans;
```

4.4 Euler's totient

```
#include <bits/stdc++.h>
using namespace std;
int nthPhi(int n) {
  int result = n;
  for (int i = 2; i <= n / i; i++) {</pre>
    if (n % i == 0) {
      while (n \% i == 0)
        n /= i;
      result -= result / i:
  if (n > 1)
    result -= result / n;
  return result;
vector<int> phiFrom1toN(int n) {
  vector<int> vPhi(n + 1);
  vPhi[0] = 0;
  vPhi[1] = 1;
  for (int i = 2; i <= n; i++)</pre>
    vPhi[i] = i;
  for (int i = 2; i <= n; i++) {</pre>
    if (vPhi[i] == i) {
      for (int j = i; j <= n; j += i)</pre>
        vPhi[j] -= vPhi[j] / i;
  return vPhi;
```

4.5 Extended Euclidean

```
#include <bits/stdc++.h>
using namespace std;
typedef long long ll;
ll extGcd(ll a, ll b, ll &x, ll &y) {
   if (b == 0) {
      x = 1;
      y = 0;
      return a;
} else {
      ll g = extGcd(b, a % b, y, x);
      y -= (a / b) * x;
      return g;
}
```

4.6 Gray Code

```
int grayCode(int nth) {
  return nth ^ (nth >> 1);
}
```

```
int revGrayCode(int g) {
  int nth = 0;
  for (; g > 0; g >>= 1)
    nth ^= g;
  return nth;
}
```

5 Geometry

6 String Algorithms

7 Miscellaneous

8 Theorems and Formulas

8.1 Binomial Coefficients

```
(a+b)^n = \binom{n}{0}a^n + \binom{n}{1}a^{n-1}b + \binom{n}{2}a^{n-2}b^2 + \dots + \binom{n}{k}a^{n-k}b^k + \dots + \binom{n}{n}b^n Pascal's Triangle: \binom{n}{k} = \binom{n-1}{k-1} + \binom{n-1}{k} Symmetry rule: \binom{n}{k} = \binom{n}{n-k} Factoring in: \binom{n}{k} = \frac{n}{k}\binom{n-1}{k-1} Sum over k: \sum_{k=0}^{n} \binom{n}{k} = 2^n Sum over n: \sum_{m=0}^{n} \binom{m}{k} = \binom{n+1}{k+1} Sum over n and k: \sum_{k=0}^{m} \binom{n+k}{k} = \binom{n+m+1}{m} Sum of the squares: \binom{n}{0}^2 + \binom{n}{1}^2 + \dots + \binom{n}{n}^2 = \binom{2n}{n} Weighted sum: 1\binom{n}{1} + 2\binom{n}{2} + \dots + n\binom{n}{n} = n2^{n-1} Connection with the Fibonacci numbers: \binom{n}{0} + \binom{n-1}{1} + \dots + \binom{n-k}{k} + \dots + \binom{0}{n} = F_{n+1} More formulas: \sum_{k=0}^{m} (-1)^k \cdot \binom{n}{k} = (-1)^m \cdot \binom{n-1}{m}
```

8.2 Catalan Number

```
Recursive formula: C_0 = C_1 = 1

C_n = \sum_{k=0}^{n-1} C_k C_{n-1-k}, n \ge 2

Analytical formula: C_n = \binom{2n}{n} - \binom{2n}{n-1} = \frac{1}{n+1} \binom{2n}{n}, n \ge 0

The first few numbers Catalan numbers, C_n (starting from zero): 1, 1, 2, 5, 14, 42, 132, 429, 1430, \dots
```

The Catalan number C_n is the solution for:

- \bullet Number of correct bracket sequence consisting of n opening and n closing brackets.
- The number of rooted full binary trees with n+1 leaves (vertices are not numbered). A rooted binary tree is full if every vertex has either two children or no children.

- The number of ways to completely parenthesize n+1 factors.
- The number of triangulations of a convex polygon with n+2 sides (i.e. the number of partitions of polygon into disjoint triangles by using the diagonals).
- The number of ways to connect the 2n points on a circle to form n disjoint chords.
- The number of non-isomorphic full binary trees with n internal nodes (i.e. nodes having at least one son).
- The number of monotonic lattice paths from point (0,0) to point (n,n) in a square lattice of size $n \times n$, which do not pass above the main diagonal (i.e. connecting (0,0) to (n,n)).
- Number of permutations of length n that can be stack sorted (i.e. it can be shown that the rearrangement is stack sorted if and only if there is no such index i < j < k, such that $a_k < a_i < a_j$).
- \bullet The number of non-crossing partitions of a set of n elements.
- The number of ways to cover the ladder $1 \dots n$ using n rectangles (The ladder consists of n columns, where i^{th} column has a height i).

8.3 Euler's Totient

If p is a prime number: $\phi(p) = p - 1$ and $\phi(p^k) = p^k - p^{k-1}$

If a and b are relatively prime, then: $\phi(ab) = \phi(a) \cdot \phi(b)$

In general: $\phi(ab) = \phi(a) \cdot \phi(b) \cdot \frac{gcd(a,b)}{\phi(gcd(a,b))}$

This interesting property was established by Gauss: $\sum_{d|n} \phi(d) = n$, Here the sum is over all positive divisors d of n.

Euler's theorem: $a^{\phi(m)} \equiv 1 \pmod{m}$, if a and m are relatively prime.

Generalization: $a^n \equiv a^{\phi(m)+[n \mod \phi(m)]} \mod m$, for arbitrary a, m and n $> log_2(m)$.

8.4 Primes

If $n=p_1^{e_1}\cdot p_2^{e_2}\cdots p_k^{e_k}$ então , then: Number of divisors is $d(n)=(e_1+1)\cdot (e_2+1)\cdots (e_k+1)$.

Sum of divisors is $\sigma(n) = \frac{p_1^{e_1+1}-1}{p_1-1} \cdot \frac{p_2^{e_2+1}-1}{p_2-1} \cdots \frac{p_k^{e_k+1}-1}{p_k-1}$
